Guatemala, November  
2006

## Instituting a standard regional monitoring system

## Outcomes Monitoring Support Program

# Outcomes Monitoring: Status & Trends in Biodiversity

Guatemala, November  
2006

Strengthening the relationship between local data collection and large-scale data representation through standardized regional biodiversity monitoring

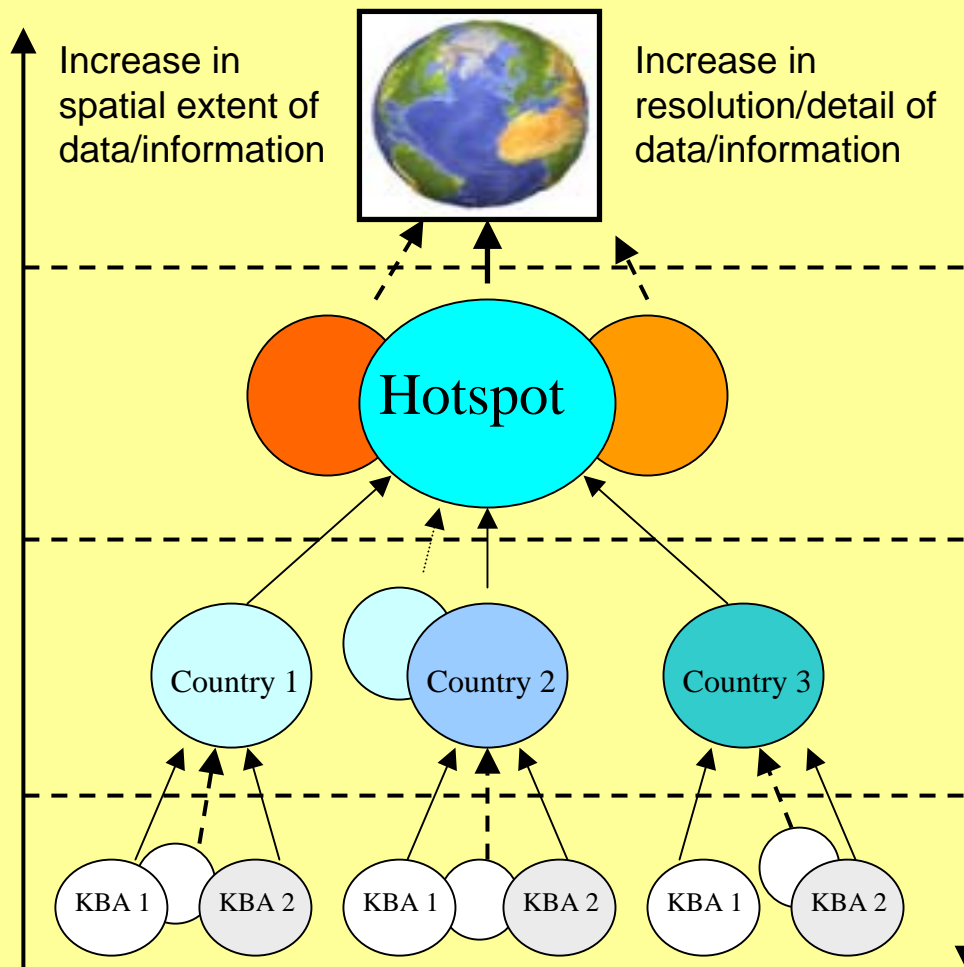

***‘from disparate data to coordinated reporting’***

# Outcomes Monitoring: Status & Trends in Biodiversity

Guatemala, November 2006

## Scales of monitoring and reporting

Regional trends identify gaps in conservation priorities at finer scales as well informs management & policy decision making

Standard & compatible local data required to report regional and global trends.

# Outcomes Monitoring: Status & Trends in Biodiversity

Guatemala, November  
2006

What is the INFORMATION relationship between different scales of monitoring and what process must be put in place for data to flow?

Field data

Species, sites and scapes data centralized in Outcomes database

----- **Filter**

Data is aggregated using Red List Index & site prioritization mechanisms (IBAs, KBAs, Eco-regions).

Aggregated species & site baseline data. Analyzed with other variables (protection & management status, habitat change)

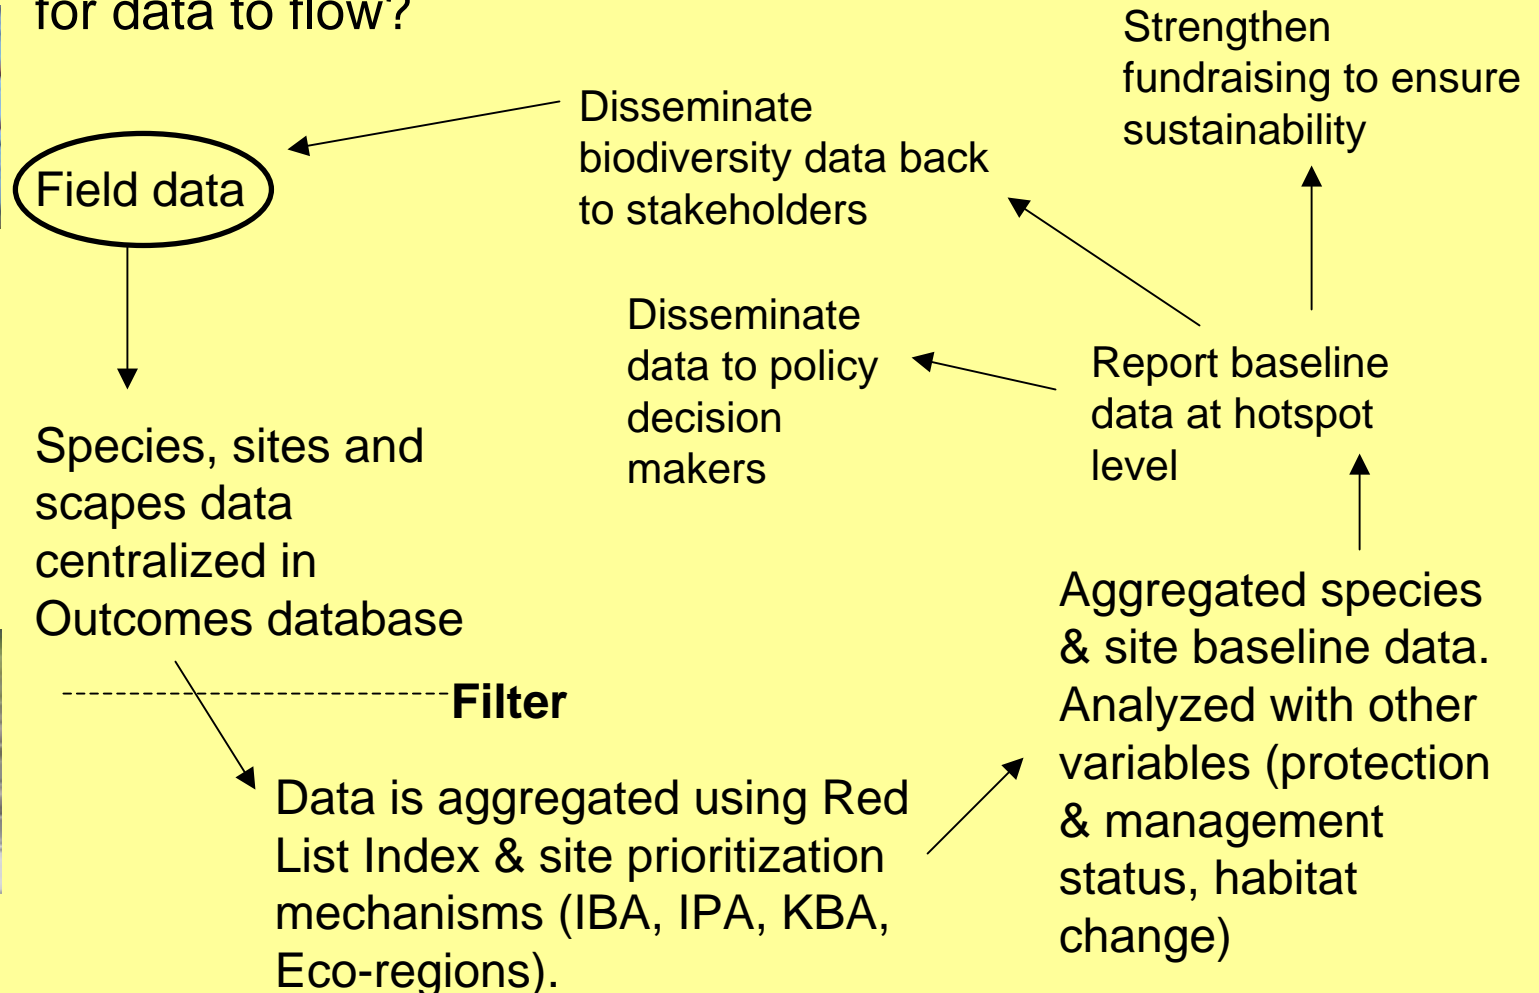

Report baseline data at hotspot level

# Outcomes Monitoring: Status & Trends in Biodiversity

Guatemala, November 2006

What is the INFORMATION relationship between different scales of monitoring and what process must be put in place for data to flow?

# Outcomes Monitoring: Status & Trends in Biodiversity

Guatemala, November  
2006

Collection of status & trend data improves our effectiveness to:

- **Track and assess trends in the status of biodiversity**
- Assist in demonstrating impact of actions and investments on biodiversity
- **Justify and direct future conservation, policy and investment decision making**
- Communicate successes and failures of conservation strategies to government agencies, investment bodies, industry and society as a whole.
- Better understand the dynamics of biodiversity components and threats and adapt accordingly.
- **Contribute to international biodiversity status reporting, e.g. Convention on Biological Diversity and the Millennium Development Goals.**

# Outcomes Monitoring: Status & Trends in Biodiversity

Seascapes**  
*Corridors Created*

**Genes**

**Biosphere**

**Increasing scale of ecological organization**

# Outcomes Monitoring: Status & Trends in Biodiversity

Guatemala, November  
2006

Indicators, defined regionally, are globally applicable measures that contribute to Convention of Biological Diversity recommendations.

- ***Core Indicators:***

- Red List Index: Change in Red List status of species
- Protected status of Key Biodiversity Areas
- Change in habitat cover of Key Biodiversity Areas
- Fragmentation of habitat in corridors

- ***Additional intervention measures:***

- Number of Protected Biodiversity Areas with governance structures & management plans in place
- Percentage of globally threatened species that have ongoing studies that focus on ecology, population, or distribution & monitoring in place

## Data collection, analysis and reporting. Examples from Madagascar and the Philippines

# Outcomes Monitoring: Status & Trends in Biodiversity

## Change in Forest Cover of Madagascar:

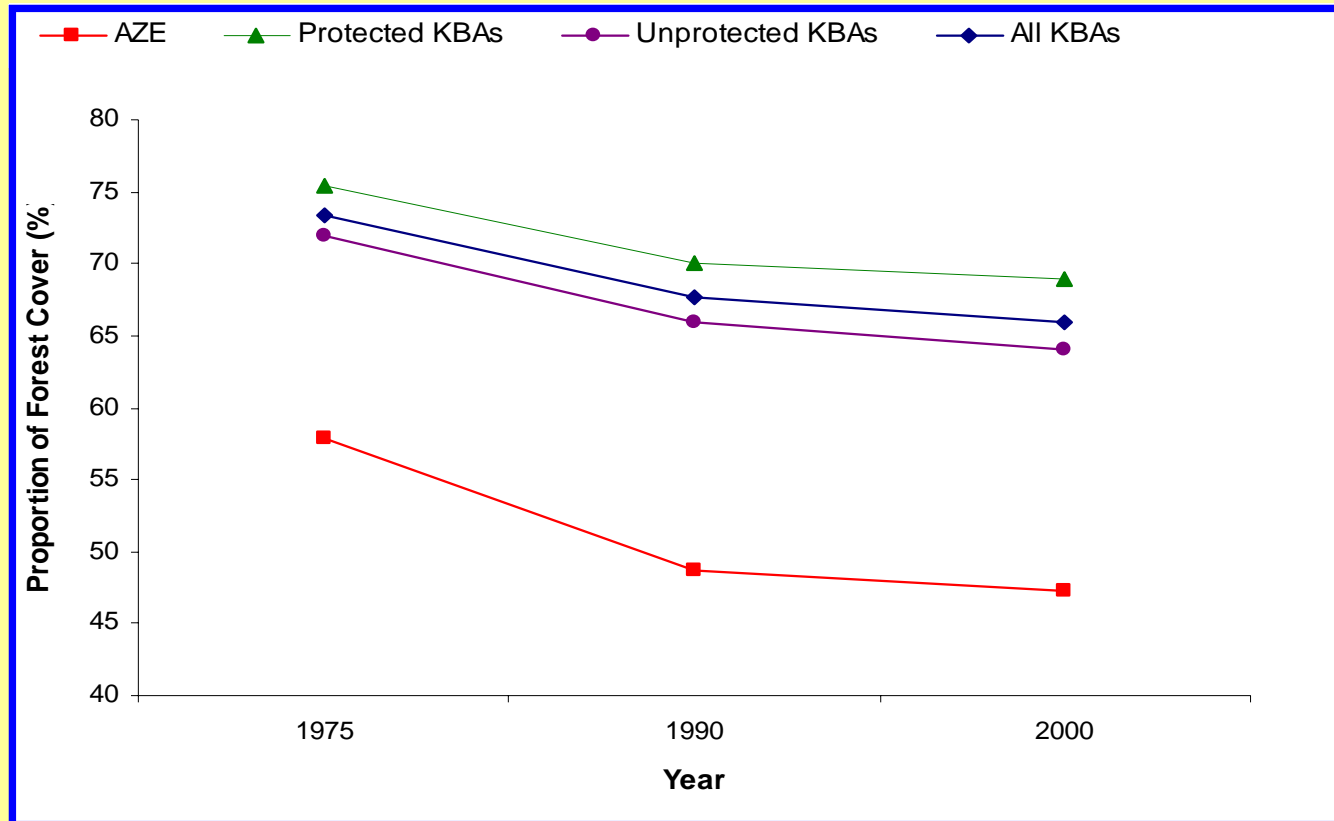

Primary habitat loss over the period of time :1975, 1990, 2000.

# Outcomes Monitoring: Status & Trends in Biodiversity

Guatemala, November  
2006

Change in Habitat Extent in Key Biodiversity Areas,  
including Alliance for Zero Extinction sites for Madagascar

*AZE sites had the highest rate of decline in the proportion of habitat cover during 1975 to 1990. During 1990 to 2000 the rate of decline slowed for all KBAs*

# Outcomes Monitoring: Status & Trends in Biodiversity

Guatemala, November  
2006

Change in fragmentation in biodiversity conservation corridors: edge indicator

a) *proportion of habitat > 1 km from a non-habitat edge*

# Outcomes Monitoring: Status & Trends in Biodiversity

Guatemala, November  
2006

Change in fragmentation in biodiversity conservation corridors: isolation indicator

*b) proportion of habitat in patches > 100 km<sup>2</sup>*

# Outcomes Monitoring: Status & Trends in Biodiversity

Guatemala, November  
2006

## *Reporting:*

Can a subset of selected CBD indicators recommended for measuring the 2010 target be adopted to track & report progress at national and regional scales?

## *Decision-making:*

How can biodiversity information be best utilized by government and investment decision makers to guide strategic conservation & sustainable development planning?

- What scale of conservation decision making (site, regional & national) and by whom?

# Outcomes Monitoring: Status & Trends in Biodiversity

Guatemala, November  
2006

Establishing National/Regional Monitoring networks to ensure sustainability and consistency in data collection and reporting.

# Outcomes Monitoring: Status & Trends in Biodiversity

Guatemala, November  
2006

Monitoring systems held together by five components:

- Key stakeholders with defined technical roles & responsibilities
- Complementary indicators with standardized measurement protocols
- Centralized & compatible data housing and analysis infrastructures
- Collaborative dissemination efforts (workshops, publications)
- Fundraising strategy driven by multiple partners

## Dissemination efforts to leverage baseline monitoring data

Leveraging and diversifying biodiversity information for multiple actors at multiple scales

Guatemala, November  
2006

## Monitoring Biodiversity Conservation Outcomes in Madagascar

**T**here is an urgent need for a global biodiversity conservation monitoring framework. Without it we cannot demonstrate that our actions are achieving the conservation outcomes we intend. The outcomes monitoring framework provides a blueprint for reporting progress in achieving quantitative conservation targets at the level of species (following the IUCN Red List of Threatened Species), sites (Key Biodiversity Areas), and landscapes (biodiversity conservation corridors).

Madagascar is a megadiversity country and a biodiversity hotspot. In 2003, its government committed to tripling the protected area network by 2006. Thus, Madagascar presents an ideal first case to apply the outcomes monitoring framework to evaluate the impact of this pledge. Here, we present systematic indicators for evaluating trends in Malagasy biodiversity over time.

## Change in Habitat Extent in Key Biodiversity Areas

Habitat loss is the key factor causing species to be threatened with extinction, so successful conservation programs habitat conversion within KBAs. Fine-resolution, low-cost satellite data can be analyzed to track habitat change in KBAs between 1975, 1990, and 2000. Figure 3 shows results in the proportion of habitat cover over this time for all KBAs and for three subsets: AZE sites, protected KBAs and unprotected KBAs. AZE sites had the highest rate of decline in the proportion of habitat cover during 1975 to 1990. During 1990 to 2000 the rate of decline slowed for all KBAs.

Figure 3. Change in habitat extent among all KBAs in three periods (1975, 1990, and 2000). Habitat cover is shown for all KBAs and for three subsets: AZE sites, protected KBAs, and unprotected KBAs. \*Data source: <http://www.biodiversityscience.org/CAS/Outcome/indicators.aspx>

## Change in Fragmentation in Biodiversity Conservation Corridors

As landscape-level conservation targets, corridors depend on connectivity to maintain the ecological processes that allow biodiversity to persist. This connectivity can be measured by indicators of fragmentation: the proportion of habitat located more than 1 km from non-habitat edge, and the proportion of habitat not in isolated patches <100 km<sup>2</sup> (Figure 4). We analyzed two corridors in Madagascar: their fragmentation has continued from 1975–2000 at a moderate rate for the edge indicator and a slow rate for the isolation indicator. Again, these indicators have important policy implications: watershed trends highlight corridors where connectivity should be maintained or increased.

Figure 4. Change in fragmentation of natural habitat between 1975 and 2000 in proportion of habitat further than 1 km from a non-habitat edge, and ii) proportion of habitat not in isolated patches <100 km<sup>2</sup>. \*Data source: <http://www.biodiversityscience.org/CAS/Outcome/indicators.aspx>

## Change in Habitat Extent in Key Biodiversity Areas

Habitat loss is the key factor causing species to be threatened, with a general habitat conversion within KBAs. Fine-resolution, low-cost habitat change in KBAs between 1975, 1990, and 2000. Figure 3 shows cover over this time for all KBAs and for three subsets: AZE sites, pre-AZE sites had the highest rate of decline in the proportion of habitat 1990 to 2000 the rate of decline slowed for all KBAs.

## Change in Fragmentation in Biodiversity Conservation

As landscape conservation targets, connectivity is an essential that allow biodiversity to persist. This connectivity can be measured proportion of habitat located more than 1 km from non-habitat edge in isolated patches <100 km<sup>2</sup> (Figure 4). We analyzed two random has continued from 1975–2000 at a moderate rate for the edge index indicator. Again, these indicators have important policy implications: where connectivity should be maintained or increased.

## The Red List Index (RLI)

The RLI measures the relative rate at which the number of species in each IUCN Red List category changes. It is calculated by tracking genuine change in species' extinction risk between Red List assessments. The overall threat status of a group determines its position on the vertical axis while the direction of the trend is determined by the genuine change in threat status of individual species in the group. For birds and amphibians, the RLI reveals deterioration in the conservation status over the last two decades, while the conservation status of mammals remained constant (Figure 1). Thus, while the mammals did not experience significant status changes over the last decade, the Red List Index reveals that as a taxonomic group, they are facing a much higher degree of threat than either birds or amphibians. Over a period of two decades, the RLI is sensitive enough to capture genuine biodiversity changes at a regional or national scale. Defining RLI should spur further investment in the conservation of species facing increased extinction risk—as has happened over the last three years in Madagascar.

Figure 1. The Red List Index (RLI) for birds, mammals and amphibians of Madagascar. An RLI value of 1.0 means that all species in the taxonomic group are least concern, a value of 0.5 indicates that all species are critically endangered, and a value of 0 indicates that all species in particular taxonomic group are Extinct. \*Data source: <http://www.iucnredlist.org>

## Change in Protection Status of Key Biodiversity Areas (KBAs)

KBAs are sites of global biodiversity conservation significance defined using standardized criteria and thresholds to guide conservation or restoration such as the establishment of protected areas. Sites identified by the Alliance for Zero Extinction (AZE) are the highest priority subset of KBAs and contain the last remaining population of one or more Critically Endangered or Endangered species. This indicator tracks the change in percentage of KBAs with official protection status. In Madagascar, 50 of 164 KBAs (30.5%) including 11 of 15 AZE sites (73%), benefit from official safeguard status (Figure 2). Seven KBAs (including the Durain/Loky-Maunamban and the Mizebe AZE sites) were proclaimed as new protected areas in 2005 and 2006 to advance the Durain Vision, illustrating how KBAs can effectively inform the identification of new protected areas.

Figure 2. Trends in the total percentage of the national key biodiversity areas (KBAs) and AZE sites under some form of legal protection for the time period 1990–2006. There are 164 KBAs currently identified across Madagascar, with 15 of these classified as high priority AZE sites. \*Data source: <http://www.iucnredlist.org>

Guatemala, November 2006

## Monitoring Biodiversity Conservation Outcomes in the Philippines

**T**here is a pressing need for a coordinated global biodiversity conservation monitoring framework. Without it, we cannot demonstrate that our actions are achieving the conservation outcomes we intend. The outcomes monitoring framework provides a blueprint for reporting progress towards quantitative conservation targets at the level of species (following the IUCN Red List of Threatened Species), sites (Key Biodiversity Areas), and landscapes (biodiversity conservation corridors).

As a biodiversity hotspot, the Philippines presents an ideal case to apply the outcomes monitoring framework. Here, we present four systematic indicators for evaluating trends in biodiversity of the Philippines.

### Change in Protection Status of Key Biodiversity Areas (KBAs)

KBAs are sites of global biodiversity conservation significance. They are defined by standardized criteria and identifiable in-situ conservation interventions such as the establishment of protected areas. KBAs help agree work done or done by the Member States, the World Conservation Union in the Philippines, in identifying Important Bird Areas (IBAs), which are a subset of KBAs for birds. Sites identified by the Alliance for Zero Extinction (AZE) are the highest priority subset of KBAs and contain the last remaining population of one or more Critically Endangered or Endangered species. By assessing the percentage of KBAs with formally protected status, we can evaluate one measure of progress towards protecting the most important diversity-generating biodiversity hotspots. Subsequent improvement of KBAs as well as strengthening management regimes of existing protected KBAs is a high conservation management priority.

In the Philippines, 47 of 128 KBAs (37.2%) benefit from official safeguard status, including 7 of 33 (21%) AZE sites (Figure 2). Thus, a total of 54 KBAs presently lack formal governmental protection. Five of these are AZE sites: Sibuyan, Mt. Apo/Magellan, South and North Cuyayan Island, Mt. Kinabalu and Mt. Bulabuk, and Sarawak Island. These sites should be considered the highest priority for immediate protection under the National Integrated Protected Areas System Act.

**Figure 2** Trends in the total percentage of KBAs (Key Biodiversity Areas) and AZE sites (Alliance for Zero Extinction) that are under some form of legal protection from 1990 to 2005. There are 128 KBAs covering significant areas in the Philippines, with 47 of them identified as high priority AZE sites.

In the Philippines, 45 of 128 KBAs (35.2%) benefit from official safeguard status.

### Change in Habitat extent within Key Biodiversity Areas (KBAs) in Palawan, Sierra Madre, and Eastern Mindanao Biodiversity Conservation Corridors

Habitat loss is a key factor causing species to be threatened with extinction, so successful conservation programs help to conserve critical biodiversity elements. Thus, evaluation, for one variable that can be analyzed to track changes over time in habitat cover. In this case we tracked change in forest cover over within KBAs between 1990 and 2000.

Figure 3 shows the proportion of habitat cover during 1990 to 2000 for all KBAs and AZE sites. While the proportion of habitat cover within KBAs in Eastern Mindanao is lower, decline between 1990 and 2000 was similar to across the three corridors. Consequently, however the rate of deforestation was much higher for the AZE sites in the Palawan and Sierra Madre corridors (see AZE activities here identified in Eastern Mindanao).

**Figure 3** Change in habitat extent between 1990 and 2000 among all of KBAs in Palawan, Sierra Madre and Eastern Mindanao and for AZE sites in Palawan and Sierra Madre.

## Utility of Outcomes data

- Promote multi – stakeholder use of biodiversity conservation status data
- Inform & direct government and donor policy and investment decision making
- Strengthen future fundraising strategies
- Gain efficiencies in delivering biodiversity conservation status trends
